Cloud Automation for MedFusion Inc

SYNECTIKS

The Ask:

Can you help us to automate our current cloud resource provisioning process?

Existing Process:

Development and Deployment teams sends an e-mail request to Data Centre Admin along with an attached form, specifying resources details. The Admin takes an approval from manager by e-mail and manually go to vsphere administration console and creates the resources one by one as per the specification. The admin allocates the IP's and set the IP's in the resources and finally e-mail to the consumer on completion. In case the resources are retired, the requestor e-mails to admin and the admin fulfills the request.

Request:

Fully automate the process to take the request from service desk and upon approval, the resources are provisioned from an automation script and send the logs to the request ticket and the procedure is set to closure with notification to requestor.

Answer:

Synectiks conceived, designed and developed a complete automation solution with the existing tools, that customer was using.

Challenges:

Customers wanted a solution based on the existing tools they have which is easy to build and maintain. Also, the solution should be able to cater any further automations that can be hooked in easily. The resource provisioning should cater not only the creations of virtual machines, but also the initial bootstrap configuration like IP/DNS/Security configuration. Customers wanted the solution to be intelligent enough to verify available capacity and create resource pool accordingly.

Solution:

Customer was using jira service desk as their ticketing tool and Jenkins for their CI/CD. We implemented a complete business process in jira in conjunction with some automation task in jenkin. Dev team sends e-mail or raise a service desk request. In case of e-mail, the service desk tickets gets automatically created. The admin would approve the request and on approval, the Jenkin job engine would trigger a provisioning job. Once the job is successful, job engine will notify the jira about the completion along with resource details. The ticket status is changed automatically and customer is informed through e-mail about the completion.

ROI & TCO:

It saved 60% time and 50% operations job. It improved the resource provisioning SLA time 80%. The solution come on top of their existing tools with some added scripts.
